

Definition: Group

A **group** is an ordered pair (G, \star) , where G is a set and \star is a binary operation on G satisfying

1. The operation is associative: $(a \star b) \star c = a \star (b \star c) \forall a, b, c \in G$
2. G has an identity: $\exists e \in G$ such that $e \star a = a \star e = a \forall a \in G$
3. Every element $a \in G$ is invertible: $\forall a \in G \exists a^{-1} \in G$ such that $a \star a^{-1} = a^{-1} \star a = e$

Theorem: Orbit-Stabilizer Theorem

Let G be a group acting on a set X , with $x \in X$. Then the map

$$G/G_x \longrightarrow G \cdot x$$

$$aG_x \mapsto a \cdot x$$

is well-defined and bijective, and therefore $|G \cdot x| = [G : G_x]$.

Proof: Let $a, b \in G$. Then

$$aG_x = bG_x \iff b^{-1}a \in G_x$$

$$\iff b^{-1}a \cdot x = x$$

$$\iff a \cdot x = b \cdot x.$$

Observe the map is well-defined by (\implies) and injective by (\impliedby) .

For surjectivity, note for any $a \in G$, $a \cdot x$ is the image of aG_x .
